Cymbachne
history
nomenclature

Abstract In Malesia there are 4 species of *Dimeria* (*Gramineae*). A brief history of the genus with a key, nomenclature, descriptions, and notes is provided. *Dimeria ciliata*, *D. dipteros*, and *D. fuscescens* are reduced to *D. chloridiformis*, *D. leptorhachis* and its var. *velutina* to *D. gracilis*, *D. monostachya* to *D. kurzii*. *Dimeria ornithopoda* var. *gracillima* is not recognised. *Cymbachne* is doubtfully referred to *Ischaemum*.

Published on 16 November 2016

INTRODUCTION

Dimeria R.Br. (*Gramineae*) is a genus with about 67 species ranging from Madagascar, India to S Korea, Marianas, and Australia. The majority (c. 34 species) occur in Peninsular India (Hackel 1889, Hooker 1896, Bor 1953, Kiran Raj 2008) indicating it to be the centre of speciation of the subtribe *Dimeriinae* Hack. In SE Asia, approximately 14 have been reported for Indo-China, Malesia, China, and the Pacific (Camus & Camus 1922, Ridley 1925, Jansen 1953, Schmid 1958, Henty 1969, Gilliland 1971, Lazarides 1980, Chen & Phillips 2006, Clayton & Snow 2010, Teerawatananon et al. 2014). In Australia there are 3 (Simon 1993) and in the Pacific (Clayton & Snow 2010) 3.

Although rather anomalous, it clearly belongs to the *Andropogoneae* Dumort. It is immediately distinct by the tenacious, espatheate, solitary or digitate racemes with solitary hermaphrodite spikelets lateral to the rachis, shortly pedicelled, laterally compressed, and florets with 2 anthers (there are some reports of 3, but this has not been seen in this study). The authorship of the subtribe *Dimeriinae* is sometimes given as C.E. Hubbard (1934), but he explicitly cited Hackel (1889).

It was first described from Australia with as the only species *D. acinaciformis* R.Br. which Brown placed between *Imperata* Cirillo and *Ischaemum* L. He also mentioned an unnamed species from India. The name alludes to the paired racemes (dimerous: δις μερις, 'two parts': 'spica duplex'). Bor (1953: 554) has suggested that Brown had inspected an abnormal specimen with 3 anthers.

It was not the first species known to Western science, though, for *Anthoxanthum avenaceum* Retz. was described in 1783 from South India, now known as *D. avenacea* (Retz.) C.E.C.Fisch. *Haplachne* J.Presl (1830) was based on *H. pilosissima* J.Presl from Luzon, the Philippines, a synonym of *D. chloridiformis* (Gaudich.) K.Schum. & Lauterb. The name means 'simple chaff' ('ἀπλοῦς ἀχνη').

Didactylon Zoll. & Moritzi (1846) was described with two species from Java, both forms of *Dimeria ornithopoda* Trin. The name refers to the paired racemes ('two fingers': δις δακτυλος). *Psilostachys* Steud. (1854: 413; non Turcz. 1843, *Euphorbiaceae*, nec Hochst. 1844, *Amaranthaceae*) with *P. hohenackeri*

Steud. was described from Canara (Karnataka) in S India. This is now *D. hohenackeri* (Steud.) Hochst. ex Miq. The name means 'glabrous spike' (ψιλος σταχυς).

Next to this Steudel (1854) recognised 6 species in *Dimeria*.

Pterygostachyum Steud. (1854: 413) was based on *P. lehmanii* Nees ex Steud. from India, now *D. lehmannii* (Nees ex Steud.) Hack. The name means 'winged spike' (πτερυγος σταχυς).

Hackel (1889) recognised 12 species, 2 subspecies, and 10 varieties.

Woodrowia Stapf (1896) from India was described in the *Agrostideae* Dumort. and compared to *Garnotia* Brongn. It was dedicated to George Marshall Woodrow (1846–1911; see Stapf 1895, Desmond 1977), the collector of the type of *W. diandra* Stapf (non *D. diandra* Griff. 1851a, b), now *D. stapfiana* C.E.Hubb. ex Pilg.

The genus was revised for India by Bor (1953) with 25 species and more recently Kiran Raj (2008) treated the subtribe with 2 genera and 43 taxa in an unpublished thesis.

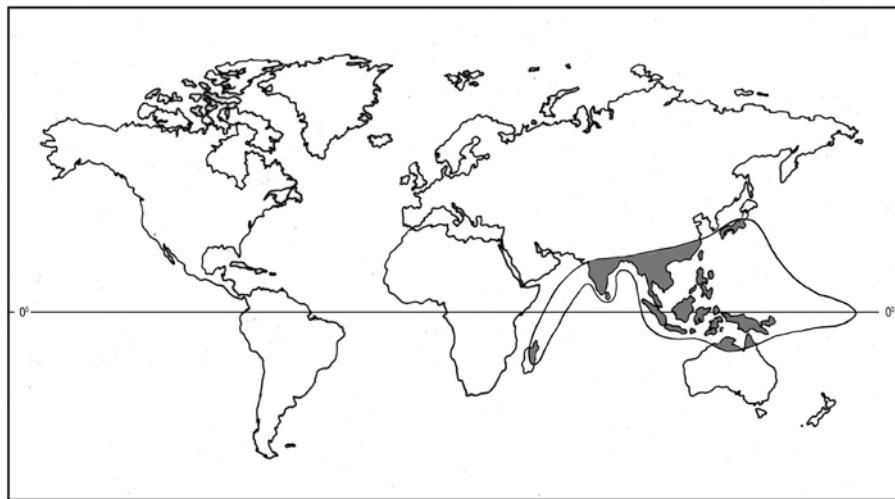

For the Malesian taxa the diagnostic characters are but few; hence several are here reduced.

For the record it may be noted that Roberty (1960) had a single species, *D. avenacea* (Retz.) C.E.C.Fisch., with 22 subvarieties in a monotypic 'Cohors' *Dimeriastreae* Roberty. He erroneously cited the Indian endemics *D. bialata* C.E.C.Fisch. and *D. fischeri* Bor for Malesia.

TAXONOMIC POSITION

The *Dimeriinae* generally have been regarded as a member of the *Andropogoneae* Dumort. with *Dimeria* as the only genus, until *Nanooravia* Kiran Raj & Sivad. (in Kiran Raj et al. 2013a, b) with one species from India was described. Affinities have been pointed out with e.g. *Ischaemum* L., *Saccharum* L., and *Sorghum* Moench. Clayton & Renvoize (1986) regarded it as derived from the *Ischaeminae* J.Presl by suppression of the sessile spikelet, as the remaining spikelets are shortly pedicelled. This might as well be a loss of the pedicelled ones, as was observed by Miquel (1851; 'rudimentary pedicels'), but by no one else. In the *Andropogoneae* reduction of the pedicelled spikelet is the usual trend, while the 'sessile' spikelets sometimes may be shortly pedicelled. The reduction of the pedicelled spikelets usually is from male, neuter, to absent.

Map 1 Distribution of the *Dimeriinae* (by Kiran Raj with kind permission).

Kellogg & Watson (1993: 296) in a phylogenetic analysis based on morphological data treated *Dimeria* as a sister group of *Cleistachne* Benth. of the subtribe *Sorghinae* Bluff et al. with both genera nesting in a *Saccharinae* clade. Estep et al. (2014) in a nuclear molecular study, however, found *Dimeria* nested in a clade within *Ischaemum*, but with little basal support, so a reduction of *Dimeria* to *Ischaemum* seems premature. Morphologically the two are very dissimilar.

Teerawatananon et al. (2011a, 2014) regarded the *Dimeriinae* as monophyletic and most related to *Eulalia* Kunth s.l. and *Ischaemum*. Kellogg (2015) actually reduced the *Dimeriinae* to *Ischaeminae*, but remarked “The subtribe lacks obvious morphological synapomorphies, though the lower glume often has a winged keel”. The latter feature is highly variable in both genera. However, she also pointed out the presence of “leaf epidermis with intercostal cells with several papillae per cell”. Whether this is indeed a synapomorphy remains to be seen.

Sections

Bor (1953) recognised three sections in India: *Annulares* Bor (type: *D. woodrowii* Stapf), *Capillares* Bor (*D. hohenackeri* Hochst. ex Miq.), and *Loriformes* Bor (*D. pubescens* Hack.), but did not account for *D. acinaciformis*, as this is an endemic of Australia, and would be the type of the autonym. Kiran Raj et al. (2015) recognised for India four sections with 12 species in sect. *Dimeria*, some of which had been placed by Bor in the *Capillares* and *Loriformes*.

In Malesia there are:

- *Dimeria*: *D. chloridiformis*, *D. dipteros* Reeder, *D. gracilis* Nees ex Steud., *D. monostachya* Reeder, *D. ornithopoda*.
- *Loriformes*: *D. kurzii* Hook.f.

Dimeria — Map 1

Dimeria R.Br. (1810) 204; Bor (1953) 553; Teerawat. et al. (2014) 137. — Type: *Dimeria acinaciformis* R.Br.
Haplachne J.Presl (1830) 234. — *Dimeria* R.Br. [sect.] *Haplachne* (J.Presl) Endl. (1836) 106. — Type: *Haplachne pilosissima* J.Presl [= *Dimeria chloridiformis* (Gaudich.) K.Schum. & Lauterb.].
Didactylon Zoll. & Moritz in Moritz (1846) 99. — Lectotype: *Didactylon simplex* Zoll. & Moritz (= *Dimeria ornithopoda* Trin.), designated by Clayton & Renvoize (1986: 349).

Annual or perennial, caespitose. Culms internodes hollow. Leaf blades linear. Ligules truncate, margin lacerate or fimbriate. Inflorescences determinate, espaltheate, composed of 1–14 digitate racemes. Spikelets numerous, hermaphrodite, solitary, lateral to and partially embedded in the rachis, secund, biseri-

ate, pedicellate, laterally compressed. Glumes more or less equal, awnless, carinate, 1–3-nerved. Lower floret epaleate, sterile, lemma awnless, 0-nerved, similar in texture to the upper one; upper lemma incised, awnless to awned from the sinus, glabrous, 1–3-nerved. Lodicules absent or very small. Stamens 2, rarely 3 (see note). Styles fused, stigmas 2. Hilum punctiform, embryo large. $x = 7, 25$.

Distribution — C. 67 species from Madagascar to S Korea, Micronesia and northern Australia. In Malesia 4 species.

Note — Brown (1810) described the type species *D. acinaciformis* with three stamens, other authors (e.g. Hackel 1889: 86 ‘certissime’) have reported two. Presl (1830) said two, his artist depicted three. Kiran Raj erroneously (fide litt.) reported the presence of 3 stamens in *D. thwaitesii* Hack.

KEY TO THE TAXA

1. Racemes 2 or more. (Rarely 1 in *D. chloridiformis*, then plants perennial; culms 0.3–1 m long; racemes rachis flattened to triquetrous, internodes 0.8–1.5 mm long; lower glumes keel puberulous to pilose (30 x!); upper glumes acute to mucronate, keel pilose (30 x!) 2
1. Racemes 1. — Annuals. Racemes rachis flattened, 0.4–0.9 mm wide. Spikelets 4.5–8 mm long. Glume keels not winged. Anthers 0.5–1.5 mm long. Malay Penins. (Kedah), Papua New Guinea 3. *D. kurzii*
2. Perennials. — Spikelets 3.3–8 mm long 3
2. Annuals. — Racemes rachis 0.1–0.4 mm wide. Spikelets 1–3.5(–4.5) mm long. Glume keels not winged. Anthers 0.25–0.8 mm long. Widespread 4. *D. ornithopoda*
3. Racemes rachis flattened, or triquetrous. Upper glumes keel winged 4
3. Racemes rachis filiform, terete. Upper glumes keel not winged. — Malay Pen. (Kedah). 2. *D. gracilis*
4. Upper glumes keel pilose (30 x!), wing absent to narrow, not rugose. — Philippines (Palawan), New Guinea 1. *D. chloridiformis*
4. Upper glumes keel ciliolate (30 x!), wing broad, rugose. — Thailand 5. *D. kerrii*

1. *Dimeria chloridiformis* (Gaudich.) K.Schum. & Lauterb.

Dimeria chloridiformis (Gaudich.) K.Schum. & Lauterb. (1900) 165. — *Andropogon chloridiformis* Gaudich. (1826) 72, 75 (nomen); (1829) 412 (descr.). — [*Dimeria avenacea* (Retz.) C.E.C.Fisch. subvar. *chloridiformis* (Gaudich.) Roberty (1960) 398, 402, nom. inval.]. — Type: *Gaudichaud* s.n. (holo P; photo in BRI, K).

Haplachne pilosissima J.Presl (1830) 235, t. 38. — *Diplachne pilosissima* (J.Presl) Trin. (1832) 336. — Type: Haenke s.n. (holo PR; photo BISH).
Dimeria fuscescens Trin. (1832) 335. — [Dimeria avenacea (Retz.) C.E.C. Fisch. subvar. *fuscescens* (Trin.) Roberty (1960) 398, 401, nom. inval.]. — Type: Wallich 8841 ex Lindley in Herb. Trinius 1253.1 (LE, microfiche IDC BT-16/1; G, K, Herb. Wallich, microfiche IDC 7394; W).
Dimeria ciliata Merr. (1914) 262. — [Dimeria avenacea (Retz.) C.E.C.Fisch. subvar. *ciliata* (Merr.) Roberty (1960) 398, 402, nom. inval.]. — Type: BS 9320 (Merrill) (PNH lost; BISH, photo in BRI, G, K; ? L, NSW).
Dimeria ciliata Merr. var. *heteromorpha* Reeder (1948) 325. — Type: Brass 7807 (holo A; BISH, BO 1864466, L, US).
Dimeria dipteros Reeder (1948) 324, t. 6. — Type: Brass 11738 (holo US; A, BO, L).
Dimeria falcata auct. non Hack.
Eulalia argentea Brongn. var. *queenslandica* auct. non Hitchc.: Hitchc. (1936) 126.

Perennials. Culms 0.3–1 m long. Nodes bearded. Ligules 0.5–1 mm long, margin glabrous (30 x!) or ciliolate (30 x!). Leaf blades 3–25 cm by 2–5(–8) mm, puberulous or pilose, sometimes glabrous. Racemes 1–6, rachis flattened, 4–15 cm long, 0.2–1 mm wide, internodes 0.8–4 mm long, margin glabrous, ciliate, or pilose (30 x!). Pedicels 0.3–1 mm long. Spikelets 3.3–4.8(–5.6) mm long. Callus hairs 0.2–1 mm long. Lower glumes keel puberulous to pilose (30 x!), apex acuminate to mucronate, mucro 0–0.2 mm long, not winged; upper glumes acute to mucronate, mucro 0–0.6 mm long, keel winged or not, pilose (30 x!), wing narrow, not rugose. Awns 4–17 mm long, incl. 0–3.5 mm long column. Anthers 0.8–3.5 mm long. 2n = 50.

Distribution — Sri Lanka, Nepal, India (Andhra Pradesh, Assam, Bengal, Kerala, Manipur, Meghalaya, Nagaland, Orissa, Tamil Nadu) to Thailand (NE: Loei; E: Chayaphum; Pen.: Satun; therefore may be expected in N Malay Pen.), N Vietnam, Micronesia (Guam, Yap), Australia (N Territory, Queensland); Malesia: Philippines (Palawan), New Guinea: Irian Jaya (Baliem River); Papua New Guinea (Central, W-, S Highlands, Western Prov.).

Habitat — Savannahs, sometimes dominant, swampy places, wet rocks, open pine or evergreen forest; 30–2530 m altitude.

Collector's notes — Erect, fairly densely tufted, culms 30–100 cm, purple. Leaves dull mid green, bluish green with silver hairs. Inflorescence yellow/green, purplish. Spikes 1–2. Anthers yellow. Style white, pale yellow.

Notes — The var. *heteromorpha* is merely a rather glabrous form with an extended wing on the upper glume.

An isotype in A of *Dimeria dipteros* is a small specimen, but with cataphylls and extra-vaginal branching, hence not an annual. There were hardly discernible wings on the glumes. Hence the species is reduced here.

The Continental Asian representatives are known as *D. fuscescens* Trin. (1832) but I have failed to find any convincing differences.

Roberty (1960: 402) cited his subvar. *ciliata* for Deccan (India) and the Philippines. The first surely is a misidentification.

Reeder (1948: 325) and Jansen (1953: 267) noted that the peduncle would be "short pubescent below the inflorescence". I have not seen this.

The development of a wing on the keel of the upper glume is apparently not such a reliable character as some keys suggest. Merrill (1914) did not note the upper glume to be winged, Reeder said prominently in upper part. Actually it may be absent to broad, while the plants in other respects do not seem to differ.

Although said to be common in e.g. New Guinea (Henty 1969: 80), only two specimens were received from K. Possible specimens in L could not be found.

2. *Dimeria gracilis* Nees ex Steud.

Dimeria gracilis Nees ex Steud. (1854) 413. — [Dimeria avenacea (Retz.) C.E.C.Fisch. subvar. *gracilis* (Nees ex Steud.) Roberty (1960) 398, 402, nom. inval.]. — Type: Macrae 229 in Herb. Lindley (holo P; CGE).
Dimeria laxiuscula Thwaites ex Trimen (1885) 272. — Type: CP 3863 (Thwaites) (holo PDA; BO, K, P).

Dimeria leptorrhachis Hack. (1889) 90 (incl. subsp. *genuina* Hack., nom. inval.). — [Dimeria avenacea (Retz.) C.E.C.Fisch. subvar. *leptorrhachis* (Hack.) Roberty (1960) 398, nom. inval.]. — Lectotype: CP 24 (Thwaites) (W 1889-0058700; iso G, K, PDA), designated by Roberty (1960: 398).
Dimeria leptorrhachis Hack. subsp. *velutina* Hack. (1889) 90. — *Dimeria velutina* (Hack.) Bor (1952 '1951') 458. — [Dimeria avenacea (Retz.) C.E.C. Fisch. subvar. *velutina* (Hack.) Roberty (1960) 399, 402, nom. inval.]. — Lectotype: Griffith 6799 (K 000245776; iso G, W 1916-0034768), designated by Teerawatananon et al. (2014: 145).

Perennials. Culms 0.45–1.4 m long. Nodes glabrous, puberulous, or bearded. Ligules 0.3–2 mm long, margin ciliolate (30 x!). Leaf blades 15–25 cm by 2–12 mm, glabrous or pilose. Racemes 3–11, rachis filiform, terete, 4–20 cm long, 0.2–0.5 mm wide, internodes 2–4 mm long, margin glabrous (30 x!), smooth (30 x!). Pedicels 0.5–2.5 mm long. Spikelets 4.5–8 mm long. Callus hairs 0.5–1 mm long. Lower glumes keel scaberulous (30 x!) or pilose (30 x!), apex obtuse to mucronate, mucro 0–0.8 mm long, winged or not; upper glumes acuminate to mucronate, mucro 0–0.5 mm long, keel winged or not, pilose (30 x!), narrow, not rugose. Awns 5–14 mm long, incl. 2.5–4 mm long column. Anthers 2–3.5 mm long.

Distribution — Sri Lanka, W India (Goa, Karnataka, Maharashtra), Burma (Tenasserim), Thailand (Trat), Cambodia (Kampong Speu), Vietnam (Dalat), Malesia: Malay Pen. (Kedah).

Habitat — On scrub, grass land, pine and dipterocarp forest, 600–975 m altitude.

Notes — The differences between *D. leptorrhachis* and its var. *velutina* is only in the pubescence of the sheaths and leaves, which is insufficient to recognise these forms at any level. The differences with *D. gracilis* were equally unimportant.

Collected in the same site in Kedah, G. Jerai, were Burkhill 3304 (L, SING) and KLU 8157 (Kassim & Carrick) (KLU).

Distribution remarkable, everywhere apparently very local.

3. *Dimeria kurzii* Hook.f.

Dimeria kurzii Hook.f. (1896) 103. — [Dimeria avenacea (Retz.) C.E.C.Fisch. subvar. *kurzii* (Hook.f.) Roberty (1960) 398, 401, nom. inval.]. — Lectotype: Kurz 2741 (K 000245781; iso G, K 000245780), designated by Teerawatananon et al. (2014: 141).

Dimeria sinensis Rendle (1904) 359. — Lectotype: Hance 1385, p.p. ('Guangzhou') (BM 000959790 ≡ -91, -92, the largest left hand culm), designated (first step) by Teerawatananon et al. (2014: 145), designated here (second step).

Dimeria monostachya Reeder (1948) 324, t. 5, f. a, b. — Type: Brass 7806 (holo A; BISH, BO, ?K, ?L, US).

Dimeria falcata auct. non Hack: Chase (1939) 313.

Annuals. Culms 0.1–0.6 m long. Nodes puberulous or bearded. Ligules 0.4–1 mm long, margin ciliolate (30 x!). Leaf blades 1.3–10 cm by 1–5 mm, pilose. Racemes 1, rachis flattened, 1.6–7 cm long, 0.4–0.9 mm wide, internodes 0.2–1.5 mm long, margin pilose (30 x!). Pedicels 0.2–0.7 mm long. Spikelets 2–4 mm long. Callus hairs 0.2–0.4 mm long. Lower glumes keel pilose (30 x!), apex acute to acuminate, not winged; upper glumes acuminate, keel not winged to winged, keel pilose (30 x!), wing narrow, not rugose. Awns (6–)9–18 mm long, incl. the (1–)2–6 mm long column. Anthers 0.5–1.5 mm long.

Distribution — India (Kerala), disjunct with Burma (Bago, Kachin, Shan, Taninthayi), Thailand (Eastern: Buri Ram, Nakhon Ratchasima, Ubon Ratchathani; Southeastern: Chanthaburi; Central: Nakhon Nayok; Penins.: Phangnga, Ranong, Satun, Songkhla), Cambodia (Stung Treng), Vietnam, S China;

Malesia: Malay Penins. (Kedah), Papua New Guinea (Western Prov.).

Habitat — Lateritic, sandy soil, dry deciduous forest, savannahs, disturbed places, edge of rice field, beaches, locally abundant, 0–1200 m altitude.

Collector's notes — Annual. Culms violet. Blades green above, pale green underneath. Inflorescence axes greenish. Glumes green, pinkish purple, violet. Awns tan, violet.

Notes — Reeder compared his *D. monostachya* to *D. sinensis* Rendle, a synonym of *D. kurzii*. The only difference outside the very disjunct distribution is that the awns are shorter than in *D. kurzii*. The isotype specimen in A does not have broadly winged upper glumes, as described. I have seen specimens with such short awns also from Vietnam (e.g. Schmid s.n. 3 Feb. 1954; P):

- . Awns 9–18 mm long, incl. 2–6 mm long column *D. kurzii*
- . Awns 6–8.5 mm long, incl. 1–2 mm long column
- *D. monostachya*

Teerawatananon et al. (2014: 138) differentiated between *D. kurzii* and *D. sinensis* by the absence or presence of a wing on the keel of the upper glume. Having studied some specimens of both species identified by them, I fail to find this difference (or any other). Indeed some of their '*D. sinensis*' are completely wingless.

Hance 1385 is the number of a species, which consists of several collections, most pertaining to *D. falcata* Hack. as was already pointed out by Rendle (1904). The lectotypification of *D. sinensis* was sorted out by Teerawatananon et al. (2014), but unfortunately without 'designated here'.

4. *Dimeria ornithopoda* Trin.

Dimeria ornithopoda Trin. (ante 24 Jan. 1820) 167, t. 14; Ridl. (1903) 274 ('*D. ornithopodioides*', sphalm.); Honda (1930) 324 [incl. forma *typica* Hack. ex Honda, nom. inval.]; Bor (1953) 572 (incl. var. *genuina*, nom. inval.). — [*Dimeria avenacea* (Retz.) C.E.C.Fisch. subvar. *ornithopoda* (Trin.) Roberty (1960) 399, 401, nom. inval.]. — Type: *Herb. Trinius* 1254.1 (holo LE, IDC microfiche BT-16/1).

Dimeria tenera Trin. (1832) 335. — *Dimeria ornithopoda* Trin. var. *tenera* (Trin.) Hack. (1889) 81. — *Dimeria ornithopoda* Trin. [var. *tenera* Hack.] subvar. *typica* Hack. (1889) 81, nom. inval. — [*Dimeria avenacea* (Retz.) C.E.C.Fisch. subvar. *tenera* (Trin.) Roberty (1960) 399, 402, nom. inval.]. — Lectotype: *Chamisso* s.n. (LE *Herb. Trinius* 1255.1, IDC microfiche BT-16/1; iso B, extant?), designated by Teerawatananon et al. (2014: 142).

Didactylon ramosum Zoll. & Moritzi (1846) 100; Buse (1854) preprint: 27; (print) 367; Miq. (1857) 479. — *Dimeria ornithopoda* Trin. var. *ramosa* (Zoll. & Moritzi) Hack. (1889) 82; Ridl. (1891) 27 ('*subramosa*'). — *Dimeria ornithopoda* Trin. [var. *ramosa*] subvar. *typica* Hack. (1889) 82, nom. inval. — *Dimeria avenacea* (Retz.) C.E.C.Fisch. subvar. *ramosa* (Zoll. & Moritzi) Roberty (1960) 399, 402, nom. inval.]. — Type: *Zollinger* 351 (holo G; K, L, U, W).

Didactylon simplex Zoll. & Moritzi (1846) 100; Miq. (1857) 480. — Type: *Zollinger* 1595 (holo P; U).

Dimeria glabriuscula F.M.Bailey (1890) 83. — Type: *Bailey* 23 (holo BRI; MEL).

Dimeria ornithopoda Trin. subvar. *imperfecta* Hack. (1889) 82. — Type: *Lobb* s.n. (holo G).

Dimeria glabra Ridl. (1925) 192. — *Dimeria ornithopoda* Trin. var. *glabra* (Ridl.) Jansen (1953) 266. — [*Dimeria avenacea* (Retz.) C.E.C.Fisch. subvar. *glabra* (Ridl.) Roberty (1960) 398, 400, nom. inval.]. — Type: SF 4674 (Burkhill) (holo SING; G, K).

Dimeria ornithopoda Trin. var. *gracillima* Bor (1953) 576. — Lectotype: *Clarke* 21084-B (K 000245790), designated by Teerawatananon et al. (2014: 143).

Annuals. Culms 0.035–0.45(–0.8) m long. Nodes bearded to glabrous. Ligules 0.2–0.5(–1) mm long, margin glabrous, ciliolate, or fimbriate. Leaf blades 1–10(–13) cm by 0.75–3.25 mm, glabrous or sparsely setose. Racemes usually 2, sometimes 3, rarely 4, rachis filiform, terete or triquetrous, 0.7–7(–8) cm long, 0.1–0.5 mm wide, internodes 1–2 mm long, margin scaberulous or ciliate (30 x!). Pedicels 0.1–0.3 mm long. Spikelets 1–3(–4.5) mm long. Callus hairs 0–0.8 mm long. Glume keels

not winged. Upper glumes acute, smooth, scabrous, ciliolate, or setose. Awn present or absent, (0–)4–6.5(–10) mm long, incl. 1–3.5 mm long column. Anthers 0.25–0.8 mm long. 2n = 14, 32.

Distribution — India to Japan, N Australia, Malesia: throughout.

Habitat — Sunny, infertile soil, grass fields, road sides, river banks, abandoned rice fields in the dry season, resistant to mowing and grazing, locally abundant, 0–1800 m altitude.

Vernacular name — Bird's foot grass.

Collector's notes — Rhizomatous [?]. Culms prostrate, geniculate. Rachis white, margins green. Spikelets purple. Glumes with green veins, sometimes purple tinged. Column purplish brown. Anthers white, yellow. Stigmas white.

Notes — This species is rather variable and Hackel (1889) optimistically and based on only a few specimens distinguished 6 varieties and 4 subvarieties, warning that intermediary forms occur. Bor (1953, 1960) for India distinguished four. Jansen (1953) for Malesia provisionally distinguished three. Duistermaat (2005) regarded them as extremes of a range and I agree. Specimens with spikelets 1–1.5 mm long and anthers up to 0.25 mm have been distinguished as var. *gracillima* Bor (1953: 576), and e.g. Teerawatananon et al. (2014: 143, lectotype!), but otherwise they cannot be distinguished. Some collections appear to be just dwarfed forms.

Forms without awns or mucronate ones (var. *glabra*) occur within the same population (see also Ohwi 1965, Duistermaat 2005), but I have not seen mixed collections. BS 336719 (*Ramos* & *Edaño*) (SING) from Luzon had spikelets without awns or with short, simple, filiform ones in the same racemes.

POSSIBLE MALESIAN TAXA

Dimeria avenacea (Retz.) C.E.C.Fisch. forma *latilanceifolia*

Roberty (1960) 398, 400, is a nom. inval., vouchered by Merrill 3226 (G, where it could not be found), Philippines, Luzon, Bataan (n.v.).

Dimeria kerrii C.E.Hubb. ex Teerawat. & Sungkaew (in Teerawatananon et al. 2011b) 151, t. 2. — Type: *Kerr* 13868 (holo K; BK, BM).

Description after Teerawatananon et al. (2011b, 2014).

Perennials. Culms up to 1.2 m long. Nodes bearded. Ligules c. 0.6 mm long, margin ciliate. Leaf blades 10–20 cm by 3–4.5 mm, hairy. Racemes 2–3, rachis flattened, 8–16 cm long, 0.6–0.7 mm wide, internodes 1.5–2 mm long, margin ciliate. Pedicels 0.8–1.2 mm long. Spikelets 5–6 mm long. Callus hairs up to 0.5 mm long. Lower glumes keels not winged; upper glumes acute to acuminate, keel winged, ciliolate, broad, rugose. Awns 12–15 mm long, incl. 2–3 mm long column. Anthers 1.8–2 mm long.

Distribution — Thailand (Peninsula: Satun) and so may be expected in the N Malay Peninsula.

Habitat — Grasslands, moist savannah, c. 50 m altitude.

OTHER SPECIES

Dimeria fischeri Bor (1953) 564. — Type: *Fischer* 133 (holo K).

Note — Roberty (1960: 398) recorded it as present in Malesia; the actual distribution is S India (Kerala, Tamil Nadu).

Dimeria scrobiculata C.B.Clarke ex Koord. (1911) 102. —

Lectotype: *Ottolander* 358 (BO), designated here.

= *Arthraxon hispidus* (Thunb.) Makino var. *hispidus*.

Fig. 1 The Zetterstedt sheet in Lund (1228279).

Cymbachne

Cymbachne Retz. (1791) was described with as the single species *C. ciliata* represented by a single (!) specimen collected by König in Bengal. Retzius material may be expected to be in Lund (LD), but it has been long lost. It was not found by Fischer (1932), but as noted by Bor (1960: 139) a specimen is present in the Zetterstedt herbarium (LD 1228279). It was annotated not by Retzius, but by Zetterstedt (Messrs. P. Frodén and P. Lassen, LD, in litt.). Bor identified it as *D. alata* Hook.f., a Sri Lanka endemic (Fig. 1, 2).

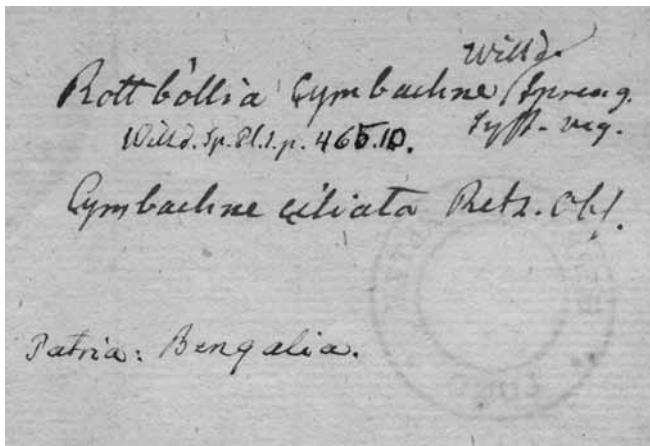

Fig. 2 The Zetterstedt label in Lund (1228279).

However, this cannot be original material. From the reference to Sprengel (1824) on the label and the absence of any mention of König it would seem that after 1824 Zetterstedt tried to identify a collection, and besides the incongruence with the original description, this cannot be the type of *C. ciliata*. That it came from Bengal, as is noted on the label, might well have been a deduction from the provenance cited by Retzius and subsequent authors.

Bor wrote "the description might easily apply to a species of *Dimeria* ... no need for a change of name". However, the description mentions the presence of paired spikelets, whereby it can never refer to *Dimeria* R.Br. (1810), which is one of the few andropogonoid genera characterised by solitary ones. *Dimeria* spikelets have only 2 stamens, 3 are described here, and depicted by Presl (1830; but described as two!). This is most fortunate, as *Cymbachne* has priority over *Dimeria*, and there is now no need for a proposal for conservation to prevent about 70 new combinations.

Probably following Bor, Clayton & Renvoize (1986: 376) have suggested that it was based on a damaged specimen of *Dimeria* R.Br. and thus it is perpetuated in the literature.

Willdenow (1797) unseen and without argumentation transferred it to *Rottboellia* L.f. as *R. cymbachne*, a superfluous name, as at the time there was no *R. ciliata*. There is no duplicate in the Willdenow herbarium (B). This combination, without any further reference, was used by Steudel (1854: 362).

Hackel (1889: 450) stated to have seen a specimen collected by König in Copenhagen (C), labelled as *Cymbachne ciliata*. He observed (my translation) that "the description is quite obscure and by no means without errors, for what he calls the female flowers seem to be nothing else than thick pedicels, remaining after the male spikelets have fallen off. Besides what else Retzius adds, agree well with the Koenig specimen and I do not doubt that I have described the same as Retzius' plant. A specimen in the herbarium Retzius, now in Lund, is to be wished for".

In C there are two (!) sheets, which makes them suspect, because a single sheet was expected in Lund:

- C10016736 with 'Rottboellia cymbachne Willd.'? and a label by Hackel: *Andropogon cymbachne* Hack., and on the back annotated as part of the Herbarium Vahl, and with the names *Andropogon cymbachne* and *Cymbachne ciliata* Retzii (K neg. 19385) and 'Konig' (Fig. 3).

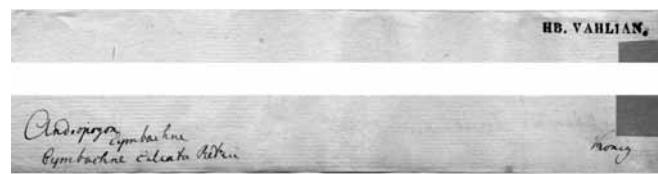

Fig. 3 Backside of C 10016736.

- C10016737 with a label by Hackel 'Andropogon cymbachne Hack. / Cymbachne ciliaris Retz.' and a reference to Hofmann Dory (??) (K neg. 19384). The 'Rottboellia' in pencil is to be neglected. A note by Clayton states "does not match description" (Fig. 4).

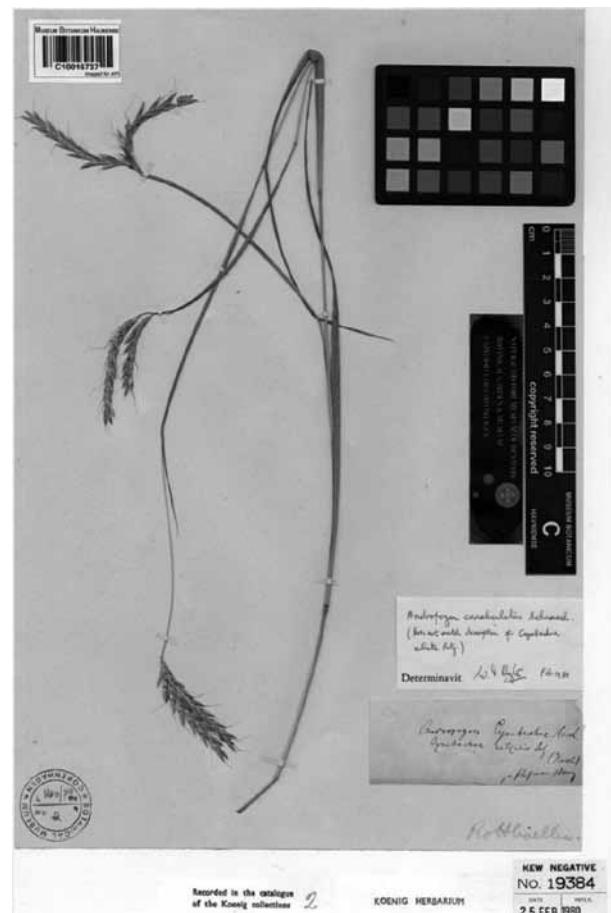

Fig. 4 Sheet C 10016737.

These specimens belong to *Andropogon canaliculatus* Schumach. This is an African species ranging from Mali to Tanzania and Zimbabwe and never could have been collected by König. Obviously, they were mislabelled and very well could be isotypes of Schumacher's species described from Ghana, the type of which has otherwise not been found as yet. However, the type of *A. eucnemis* Trin. (1832) may very well be an isotype of this, and is here designated as the neotype.

Note that later typifications do not make a name superfluous (ICN Art. 52, Note 2).

Hackel for some reason with a query included *Arthrostachys* Desv. (1831) with *A. gracilis*. This was described without prove-

nance or collector and is immediately distinct by the articulate inflorescence axes. It was not mentioned by Steudel (1854). Clayton & Renvoize (1986: 349) and Soreng & Pennington (2003) regarded it as a synonym of *Andropogon* with which I can agree. *Arthrostachya* Link (1827) is not an earlier homonym (Art. 53.3.Ex.12).

The undaunted Roberty (1960) not having seen the type, either, nevertheless accepted *Cymbachne* for 8 Asian and African species with 9 varieties and 72 subvarieties, which others have regarded as taxa belonging to *Andropogon* (incl. *Arthrostachys* Desv., *Diectomis* Kunth, *Homoeatherum* Nees, and *Pollinia* Spreng., p.p., *Rottboellia* auct.).

It may be noted that Palisot de Beauvois (1812: 109, 159) mentioned a “*Cymbachne Lour.*”. This is an error for *Stegosia* Lour. From the diagnosis and description I have the impression that he had an unawned species of *Ischaemum* (*I. muticum* L.? before him).

Cymbachne Retz. (1791) 36. — Type: *Cymbachne ciliata* Retz.

Cymbachne ciliata Retz. (1791) 36; Roberty (1960) 251 ('*ciliaris*'). — *Rottboellia cymbachne* Willd. (1797) 465, nom. superfl. — *Cymbachne alata* P. Beauv. (1812) 159, nom inval., in syn. — *Andropogon cymbachne* [Willd.] Hack. (1889) 450, nom. nov., non *A. ciliatus* Ell. (1816), nec Thunb. (1784a) 903; Thunb. (1784b) 40. — Type: *J. König s.n.* (LD, not found), Bengal.

= ? *Ischaemum muticum* L.

Arthrostachys Desv. (1831) 74. — Type: *A. gracilis* Desv.

Arthrostachys gracilis Desv. (1831) 74, t. 6, f. 2. — Type: not indicated (?P, P-JU, PC).

= *Andropogon* L.

Andropogon canaliculatus Schumach. (1827) 52. — Type: not indicated, unknown (expected in C, not found, see IDC 2203, Herb. Isert & Thonning; Hepper 1976: 142), Ghana. — Neotype: *Thonning s.n.* (holo LE), Ghana, designated here.

Andropogon eucnemis Trin. (1832) 275. — Type: *Thonning s.n. in Herb. Trin. 201 ex Herb. Hornemann* (holo LE; IDC microfiche BT-16; not in C), Ghana. Possibly homotypic with *A. canaliculatus*.

Plants perennial. Racemes 2(–3). Internodes of rachis clavate, much wider than the gap between them and the pedicels. Sessile spikelet 4–6 mm long, lower glume not pitted, deeply grooved ('canalicate'). Pedicelled spikelets well-developed, awnless (briefly mucronate).

Acknowledgements Many people assisted me during this study. Many thanks to Dr. I. Friis (C) for comments on Thonning collections, Mr. P. Frödén (LD), Dr. M.S. Kiran Raj (CALI, Department of Botany, Sree Narayana College, Cherthala – 688 582, Alappuzha, Kerala), Mr. P. Lassen (LD), Mr. P.O. Ryding (C), Dr. M. Sivadasan (KSU), and the institutes that allowed me to study their specimens: A, AMD, BIOT, BISH, BO, BORH, K, KEP, L, MEL, NSW, P, PNH, PTBG, SAN, SAR, SING, SINU, SPN, U, W, WAG.
