**Thunbergia impatienoides (Acanthaceae), a new species from Thailand**

C. Suwanphakdee 1, 2, S. Vajrodaya 1

**Key words**

new species, pollen, Thailand, Thunbergia

**Abstract**

A new species, *Thunbergia impatienoides*, was discovered from Thailand and is here described. Detailed descriptions including pollen and seed morphologies, distribution, ecology and illustration are provided.

**Published on** 30 April 2018

---

**INTRODUCTION**

*Thunbergia* is a large genus of *Acanthaceae* subfamily *Thunbergioideae* s.lat. (Brummitt 1989, Takhtajan 1997, Schönenger & Endress 1998), consisting of c. 100 species distributed in tropical and subtropical regions of Africa, Madagascar, Asia and Australia (Borg et al. 2008). The members of *Thunbergia* differ from most other *Acanthaceae* mainly in their lack of retinacula and cystoliths, their twining habit (a few species are erect), large floral bracts and bracteoles (prophylls), reduced calyx and lack of an endothecium (Lindau 1895, Bremerkamp 1953, Schönenger & Endress 1998).

The morphological characters of Asian *Thunbergia* are: Perennial herbaceous or woody climbers, shrubs, rarely erect or trailing herbs without cystoliths. The leaves are always simple and with a petiole, they are opposite, ovate or lanceolate to hastate or sagittate and their margins are entire to lobed or dentate. The flowers are pedicellate, axillary, solitary, paired, up to four arranged in fascicles or with many flowers in racemes with leaf-like bracts. The bracteoles are paired and enclosing the calyx and most or all of the corolla tube, sometimes fused on one side and persistent. The calyx is annular and much shorter than the bracteoles, subentire, undulate or 5–20-toothed or sinuate. The corolla forms a straight or curved tube. The tube is cylindrical, ventricose or gradually widened towards its apex, ± equally 5-lobed, spreading or recurved and contorted in bud. The stamens are didynamous and inserted near the base of the corolla tube. The anthers are 2-thecous, oblong or ovoid, ± spurred at base, and ± bearded. The disk is short and annular or pulvinate. The ovary is ovoid and consists of 2 locules and has 2 ovules per locule. The style is glabrous or pubescent. The stigma is funnel shaped, bilobed or 2-cleft, and entire or fringed. The fruit is a woody capsule, subglobose at the base and with an elongated beak. Each capsule has 2–4 seeds which are hemispherical, smooth or sculptured and without retinacula (Imlay 1938, Ji et al. 2011, Adhikari et al. 2013).

The pollen of *Thunbergia* species are spheroidal, with the spiraperturate and the exine ornamentation being psilate, granulate or rarely baculate. This pollen type is very special in this family and has been considered to represent a primitive condition (Lindau 1893, Bremerkamp 1955, Raj 1961, Erdtman 1969, Hong-Pin & Chia-Chi 2005). In Thailand, 13 species were previously reported. Eight species were recorded as *T. coccinea*, *T. erecta*, *T. fragrans*, *T. grandiflora*, *T. hossei*, *T. laurifolia*, *T. nivea* and *T. similis* (Imlay 1938). Later, *T. papilionacea* was reported (Norsaengsri & Tatana 2012). And then the checklist of Thai plant names was made. Eleven species including native and introduced species were enumerated as *T. affinis*, *T. alata*, *T. coccinea*, *T. colpifera*, *T. erecta*, *T. fragrans*, *T. grandiflora*, *T. hossei*, *T. laurifolia*, *T. nivea* and *T. similis* (The Forest Herbarium 2014).

While preparing a treatment of *Thunbergia* for the Flora of Thailand, the beautiful pink flower of this new species attracted our attention.

**Thunbergia impatienoides** Suwanph. & S. Vajrodaya, sp. nov. — Fig. 1–4; Map 1

Markedly differing from *T. fragrans* Roxb. by having terete stem with 2-furrows (vs 4-angled), terete petiole with a furrow (vs 4-angled), terete pedicel (vs 4-angled), ovate 5–7–5 7–5 named bracteoles (vs cordate 10–12–12 named ), involute calyx (vs revolute), magenta to pink (vs white), anther theca rounded (vs mucronate theca), stigmas magenta to pink (vs white), pollen smaller (42–44 ± 0.67 vs 54–56 ± 0.67 µm) and reticulate ornamentation on seed surface (vs glabrous with long papillae.). — Type: C. Suwanphakdee 523 (holo BKF; iso BK, BKF, K, KKK, L, QBG), Thailand, Kanchanaburi, Srisawat, Khao Pu, Salakpra Wildlife Sanctuary Park, 26 Oct. 2016.

**Etymology:** The specific epithet refers to the gross appearance of its flower which is quite similar to a common ornamental balsam, *Impatiens walleriana Hook.f.* (*Balsaminaceae*).

Woody twiner with rootstock, scabrous-stigose in almost all parts. Stems several, slender with runners, terete with 2-furrows. Leaves light green; petiole, 0.7–1.0 cm long, with a furrow. *Lamina* elliptic to elliptic-oblong, 4.0–4.5 by 1.0–2.0 cm, slightly coriaceous, base cordate or slightly hastate, apex acute or mucronate, margin strigose, veins 5–7, palmate arranged. Flower axillary, solitary; salver-form, 3.0–5.0 cm diam, magenta to pink with yellow throat; pedicel: 1.5–2.5 cm long, terete; bracteoles ovate, 1.5–2.0 by 1.0–1.5 cm, 5–7–nerved, glabrous on adaxial side, base rounded, apex mucronate, margin strigose; calyx: longer than ovary, involute, subequal, 13-toothed, 2.0–4.0 mm long; corolla tube: slender ventricose, 2.0–3.0 cm

Suwanphakdee 523 (BK, BKF, K, KKV, L, QBG)). — Photos: C. Suwanphakdee.
long, whitish pale pink, densely glandular hairs outside, glabrous inside; corolla lobe fan-shaped, 2.0–2.5 by 1.5–2.0 cm, slightly overlapped, covered with glandular hairs, abaxial surface slightly hirsute, margin repand; stamens erect, densely glandular hairs at the filamentous base, basal theca rounded; shorter stamens filament c. 3 mm long, anther c. 2 mm long; longer stamens 2–3: filament c. 6 mm, anther c. 2 mm long; disk thin and white; pollen grains in monad, spheroidal, 42–44 ± 0.67 µm diam with spiraperturate aperture. Ovary ovoid with beaked, 2.0–3.0 by 1.0–2.0 mm and forming 4-lobed, style 2.0–2.5 cm long, stigma bilobed, pink or purplish and exert at anthesis. Fruit a capsule, hirsute, basal part 1.0–1.2 by 0.7–0.8 cm, beak 1.3–1.5 cm with pedicel 1.5–2.8 cm long, thick upward. Seed globose to subglobose, 3.5–4.0 mm diam, seed coat with regular reticulate ornamentation.

Distribution — Endemic to Thailand (border of northern and western Thailand in Tak province and in western Thailand in Kanchanaburi and Ratchaburi provinces).

Habitat & Ecology — In shaded area in dipterocarp and mixed deciduous forests. Flowering: November to January; fruiting: December to February.

Notes — Based on gross morphological characters Thunbergia impatienoides is similar to T. fragrans but differ in having runner stems which is unique. The stem is terete with two furrows (one on each side) and the petiole has a furrow. The flower, which is very showy, is always presented as solitary in the leaf axil. It has an attractive and for Asian Thunbergia unseen pink colour. The distinguishing flower colour characters are dark purple or magenta in flowering bud and turning to pink when mature. The pedicel is rounded and scabrous. The flower is salver-shaped when mature. The corolla lobe is fan-shaped. The five stamens are uniformly didynamous with two shorter and three longer ones. The base of the theca is rounded (usually spurred in Thunbergioideae). The capsule is hirsute and not glabrous and waxy as in T. fragrans (compared in Table 1). The seed of both species are similar but the surface is reticulate in T. impatienoides and long papillate in T. fragrans (Fig. 3). The pollen grains are spheroidal monads. The aperture is spiraperturate which is the common character of Thunbergia. The pollen ornamentation is baculate with fossula. The difference of pollen morphology between T. impatienoides and related species is the size (42–44 ± 0.67 µm vs 54–56 ± 0.68 µm) which significantly supports T. impatienoides to be new to science. The pollen morphological characters of both species are shown (Fig. 4).
